

# An Experimentalist's View of the Role of Theory in Moving Up the Materials Pyramid

Digital Design of Materials Workshop  
Boston University  
September 27-29

*B. C. Sales*  
*Correlated Electron Materials Group*  
*Materials Science and Technology Division*  
*Oak Ridge National Laboratory*

# Outline of Presentation

- Overview of Correlated Electron Materials Group- Who we are and what we do. (Where I am coming from)
- New Materials and The Materials Pyramid
- An experimentalist's perspective of the role of theoretical approaches in the discovery of new materials
- Issues with Digital Design of Materials
- Theoretical successes
- Examples of the importance of an accurate crystal structure and/or composition –Fe based superconductors
- Historical Example: A “new” Permanent Magnet  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Importance of “Mesoscale” ( metallurgy, microstructure, defects) in magnetic performance of  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Screening guide for identifying superconductors with an unusual pairing mechanism

### Complex electronic and magnetic materials relevant to energy technology:

- **thermoelectrics** (transition metal compounds, heat transport, phonons)
- **superconductors** (iron pnictides and selenides, cuprates, magnetism)
- **permanent magnets** (non-rare earth alternatives)
- **unusual magnetic ground states** (helimagnets, frustration)

Materials synthesis and single crystal growth; structural, thermal, magnetic, transport properties; chemical manipulation of physical properties; materials and samples relevant for neutron scattering experiments.

# We grow unique crystals:

## *Science Driven Synthesis*

Relationship between dielectric constant and carrier mobility?  
Magnetic fluctuations and superconductivity?  
Magnetic fluctuations and thermal conductivity?  
Microscopic origin of low thermal conductivity in (Ag,Sb) Te crystals?  
Why does SrTcO<sub>3</sub> magnetically order at such a high temperature? (T<sub>N</sub> = 1000 K)

**BaFe<sub>12</sub>O<sub>19</sub>**  
permanent magnet  
room temp multiferroic  
grown under 100 bar  
oxygen pressure

**AgSbTe<sub>2</sub>**

**Mo<sub>3</sub>Sb<sub>7</sub>**

**FeTe<sub>0.75</sub>Se<sub>0.25</sub>**

# Structure of Presentation

- Overview of Correlated Electron Materials Group- Who we are and what we do. (Where I am coming from)
- **New Materials and The Materials Pyramid**
- An experimentalist's perspective of the role of theoretical approaches in the discovery of new materials
- Issues with Digital Design of Materials
- Theoretical successes
- Examples of the importance of an accurate crystal structure and or composition –Fe based superconductors
- Historical Example: A “new” Permanent Magnet  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Importance of “Mesoscale” ( metallurgy, microstructure, defects) in magnetic performance of  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Screening guide for identifying superconductors with an **unusual pairing mechanism**

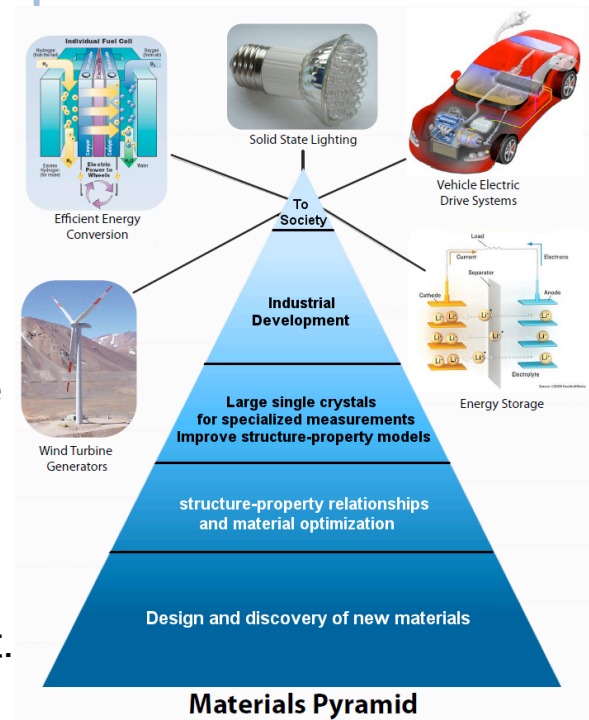

# Where do new materials come from?

18 years

# Moving up the Materials Pyramid

1. Identify a scientific or technological problem that would benefit from a new material
2. Study the literature to learn which materials do the job pretty well. Identify shortcomings and how those shortcomings might be addressed, and identify a candidate in the lower tier of the pyramid that might do it. (Crystal chemistry rules, phenomenological rules)
3. Form a team of researchers whose specialties and interests are complimentary, make the material and test to see if your idea is right. Include theory to help interpret your results.
4. Make the new material in the form needed to determine if the material has any chance of being useful in the device of interest.
5. Transfer new material to industry and eventually to society

**Physics Viewpoint:**

- Screening guide for identifying superconductors with an unusual pairing mechanism

# An Experimentalist perspective on theory and Materials Discovery

## (Inorganic Crystalline Materials)

### Different classes of theory and models:

- a) **Density Functional Theory**- can sometimes predict properties (before experiments done!)- PbSe, some ferroelectric structures are example. Needs to know accurate positions of atoms and precise stoichiometry (**accurate crystal structure**)
- b) **LDA +U** - sometimes gives interesting results that helps interpret known experimental data. Results sometime suggest new experiments.
- c) **Dynamical Mean Field Theory**- a serious attempt to develop techniques to treat strong correlations. Seems to stress correlations even when experimental data suggests otherwise. Helpful at understanding but not useful for finding new materials.
- d) **Model Hamiltonians**- useful for providing insight into general behavior of complex correlated materials- not particularly useful at finding new materials
- e) In general, theory not good at predicting new crystal structures- except perhaps in very simple cases- elements or simple cubic compounds. Some interesting results in literature- Zunger correctly accounted for 95% of structures of 565 binary AB compounds using pseudopotential radii [PRB **22** (1980) 5839] -crystal structure energy scale  $10^{-3}$ - $10^{-4}$  of cohesive energy

# Structure of Presentation

- Overview of Correlated Electron Materials Group- Who we are and what we do. (Where I am coming from)
- New Materials and The Materials Pyramid
- An experimentalist's perspective of the role of theoretical approaches in the discovery of new materials
- **Issues with Digital Design of Materials**
- Theoretical successes
- Examples of the importance of an accurate crystal structure and or composition –Fe based superconductors
- Historical Example: A “new” Permanent Magnet  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Importance of “Mesoscale” ( metallurgy, microstructure, defects) in magnetic performance of  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Screening guide for identifying superconductors with an unusual pairing mechanism

# Serious Real-World Issues With Computational Design of Materials

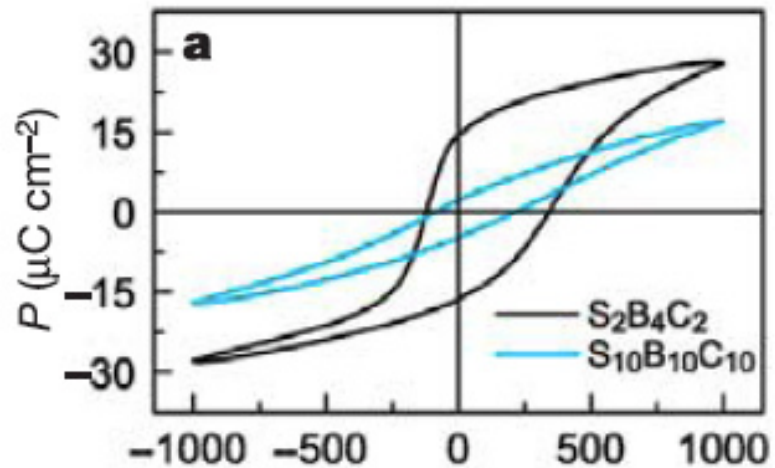

1. Defects (vacancies, twins, chemical inhomogeneities) often dominate many material properties- even more so for correlated materials
2. Many very useful, and not so exotic materials are not equilibrium phases and are metastable (**phases will be missed in theoretical phase diagrams**):
  - Steel
  - PZT (piezoelectric)
  - Glass
  - Plastics
  - Most composites
  - Diamond
  - Highly doped Silicon
  - etc

# Structure of Presentation

- Overview of Correlated Electron Materials Group- Who we are and what we do. (Where I am coming from)
- New Materials and The Materials Pyramid
- An experimentalist's perspective of the role of theoretical approaches in the discovery of new materials
- Issues with Digital Design of Materials
- **Theoretical successes**
  - Examples of the importance of an accurate crystal structure and or composition –Fe based superconductors
  - Historical Example: A “new” Permanent Magnet  $\text{Nd}_2\text{Fe}_{14}\text{B}$
  - Importance of “Mesoscale” ( metallurgy, microstructure, defects) in magnetic performance of  $\text{Nd}_2\text{Fe}_{14}\text{B}$
  - Screening guide for identifying superconductors with an unusual pairing mechanism

# Some theoretical successes at predicting materials properties

1. PbSe is a good thermoelectric material at high temperatures (Singh)
2. Ferroelectric superlattices (Rabe, Vanderbilt, Spaldin)- polarization enhancement in asymmetric superlattices
3. Topological insulators,  $\text{Bi}_{1-x}\text{Sb}_x$ ,  $\text{Bi}_2\text{Se}_3$ , etc.

- An experimentalist's perspective of the role of theoretical approaches in the discovery of new materials
- Issues with Digital Design of Materials
- Theoretical successes
- Examples of the importance of an accurate crystal structure and or composition –Fe based superconductors
- Historical Example of Finding a New Material: A “new” Permanent Magnet  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Importance of “Mesoscale” ( metallurgy, microstructure, defects) in magnetic performance of  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Screening guide for identifying superconductors with an unusual pairing mechanism

# Importance of Correct Composition

1. FeSe is a 7 K superconductor, initial electronic structure calculations suggested that FeTe should be a better superconductor- however **FeTe doesn't exist- what forms is  $\text{Fe}_{1.07}\text{Te}$**
2. Can illustrate significance of excess Fe in  $\text{Fe}_{1+x}\text{Te}_{0.75}\text{Se}_{0.25}$  exposing crystals to Te vapor at low temperatures.

# Importance of Correct Crystal Structure in Understanding/Predicting Properties

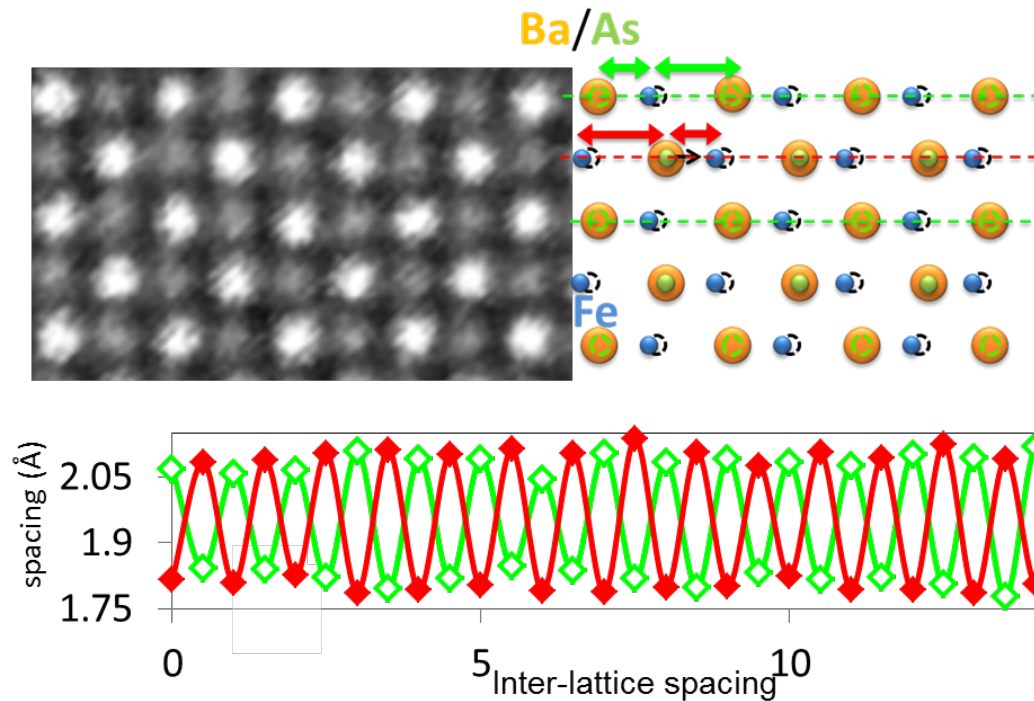

1.  $\text{BaFe}_2\text{As}_2$  is the parent phase of several electron and hole doped Fe based superconductors ( $\text{BaFe}_{2-x}\text{Co}_x\text{As}_2$  or  $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$ )
2. Single crystal and powder structural data are consistent with  $\text{BaFe}_2\text{As}_2$  having the tetragonal  $\text{ThCr}_2\text{Si}_2$  structure- but this material has very strong magneto-elastic coupling a striking elastic properties- even at room temperature. What is the local structure of  $\text{BaFe}_2\text{As}_2$  at room temperature.

Fernandes et al. PRL **105** (2010) 157003

# Evidence that $\text{BaFe}_2\text{As}_2$ is not perfectly tetragonal at room temperature

**Claudia Cantoni**

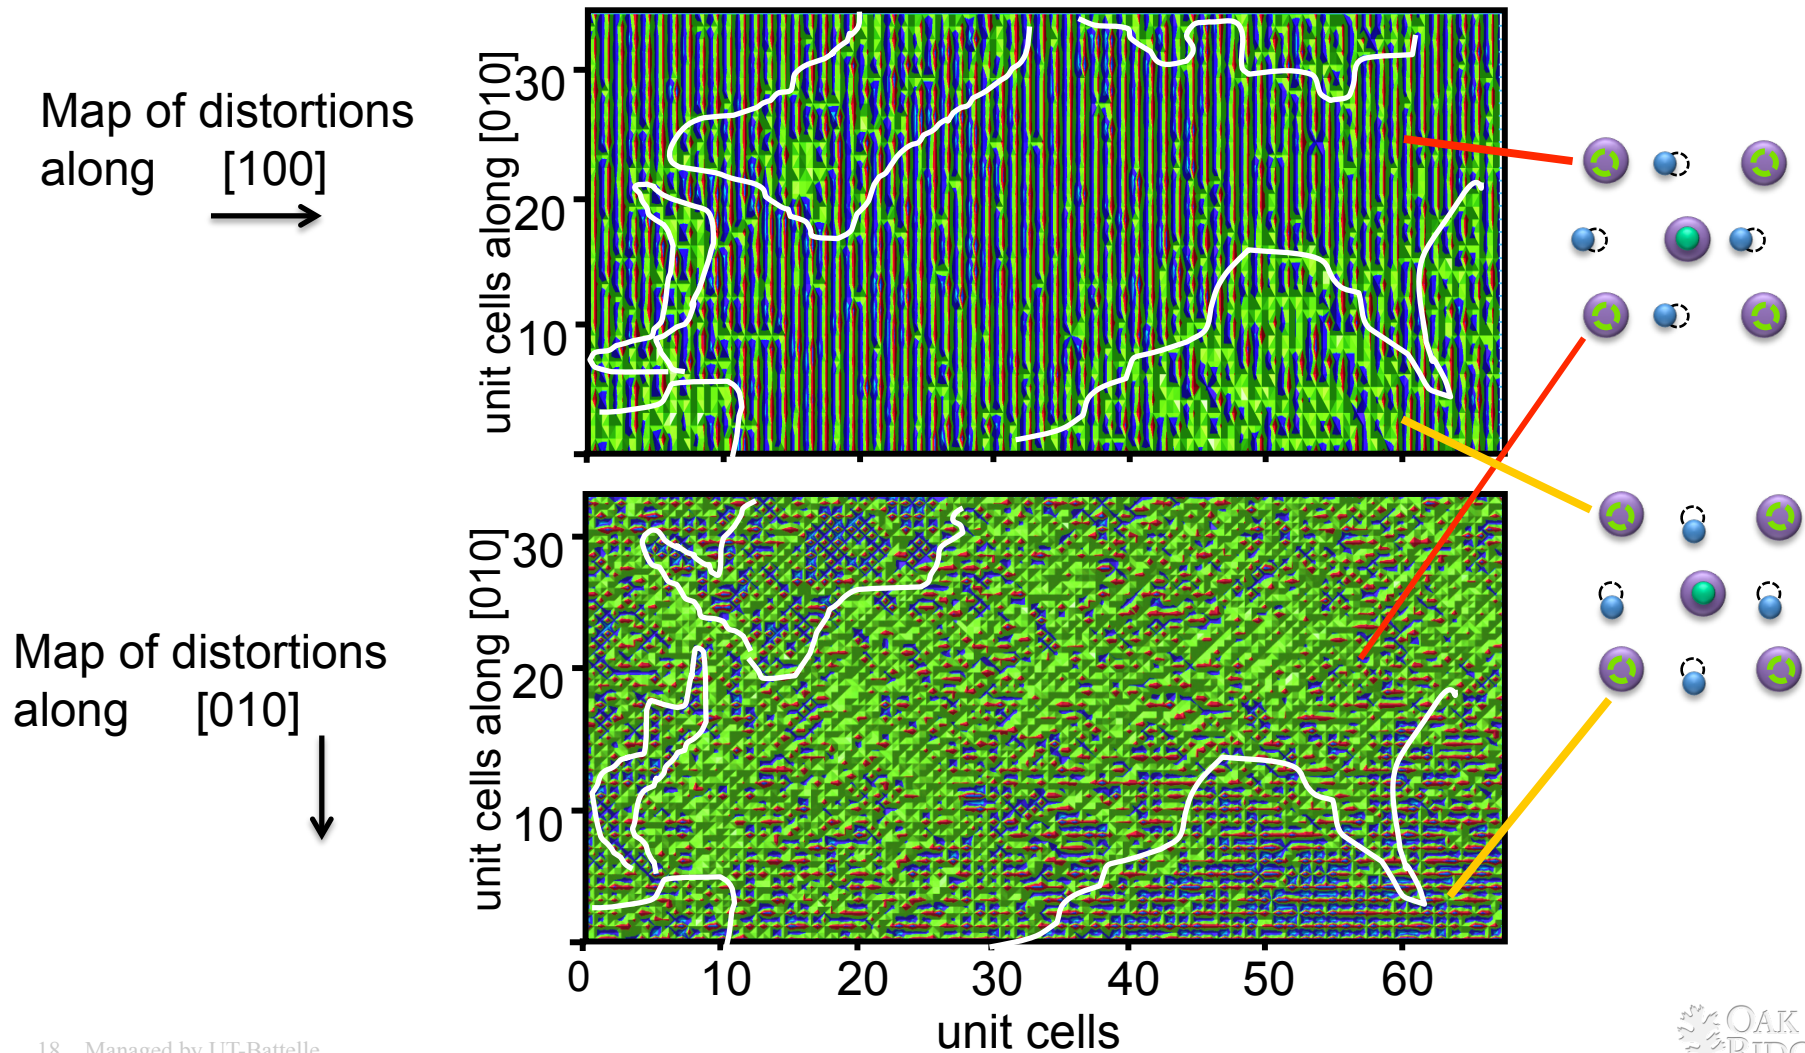

17 Managed by UT-Battelle  
for the U.S. Department of Energy

Careful Analysis of Images indicate Fe layer shifted about 0.1 Å along  
Either [100] or [010] directions- Domains  $\approx$  12 nm in size

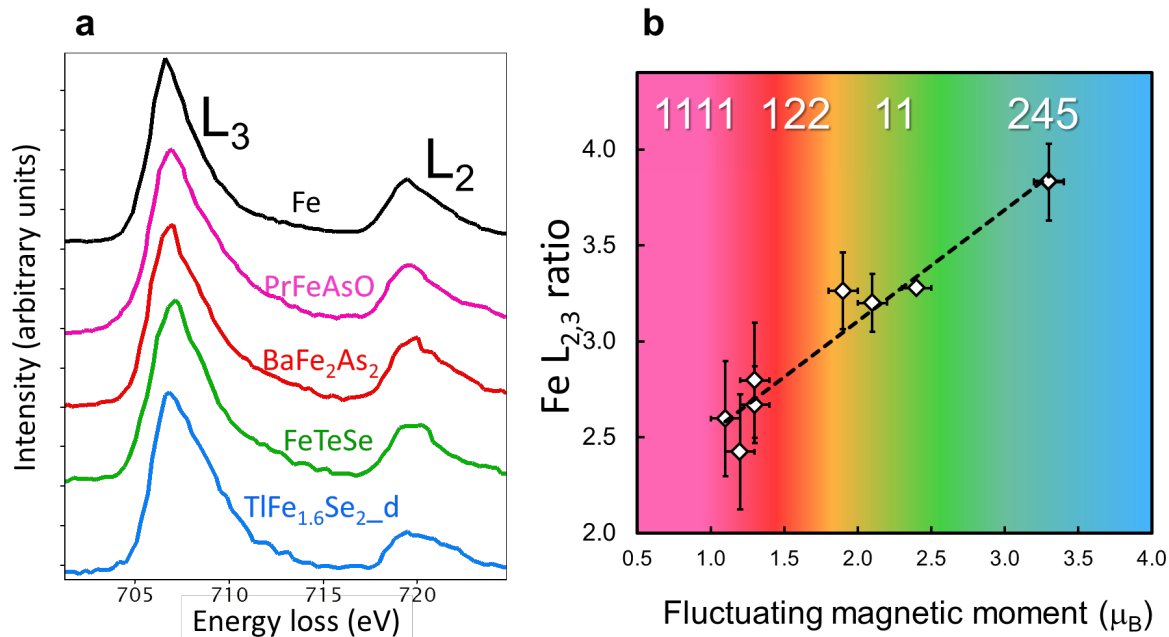

Domains are ~ 10-20 nm in size!

**blue ordered regions:** modulated interlattice spacing along the probed direction

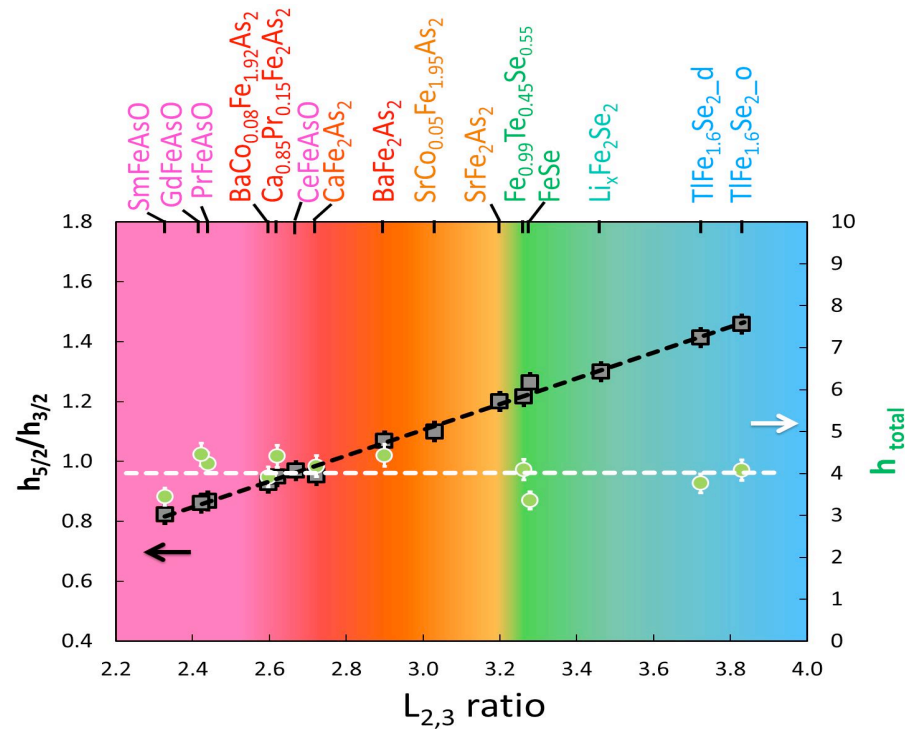

**green, disordered regions:** non-modulated interlattice spacing along the probed direction

**Empirical Correlation between  $L_3/L_2$  Ratio, as measured with EELS and Fe Magnetic Moment**  
**-useful for family of similar Fe compounds with same formal oxidation state and local environment**

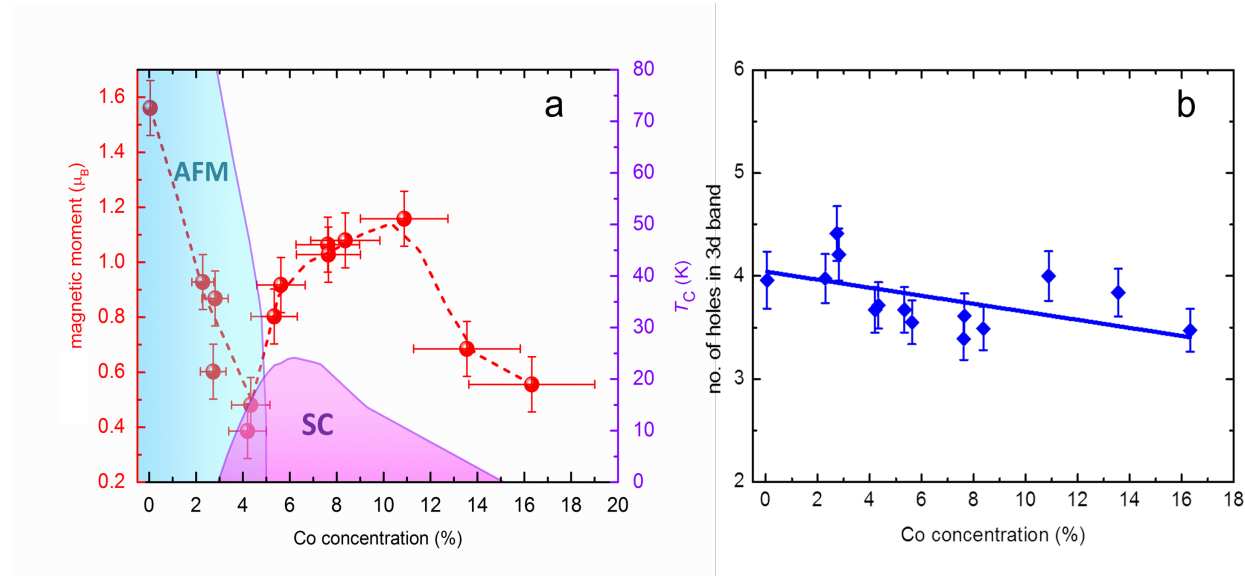

# Better theoretical justification for using $L_{23}$ Edge Spectra to obtain (1) Total number of holes in d band and (2) changes in distribution of same number of electrons within 3d orbitals

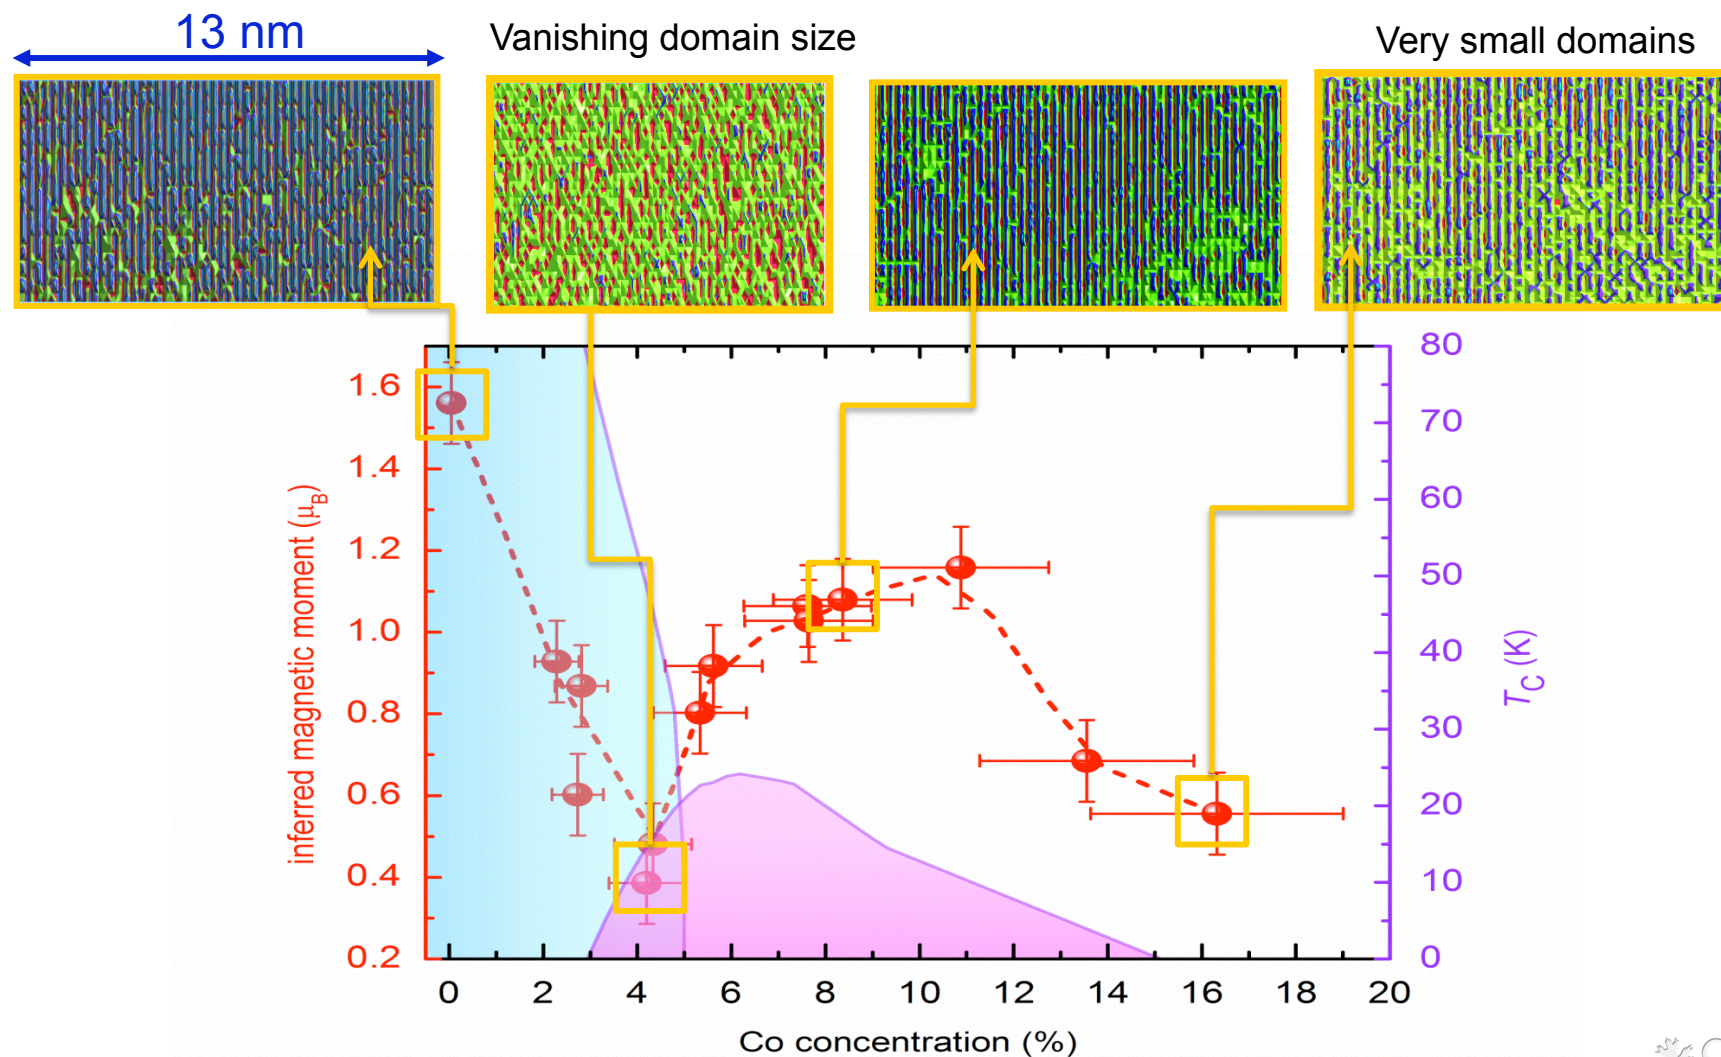

$$\frac{h_{5/2}}{h_{3/2}} = \frac{1}{6} \left[ \frac{5I_{L_3} \omega_{L_2}}{2I_{L_2} \omega_{L_3}} - 1 \right]$$

# Careful Examination of EELS data from Series of $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ Crystals

Minimum in variation of Fe moment with Co doping  
minimum value near “Lifshitz concentration”

# Distorted domains correlate with Fe local magnetic moment

# Structure of Presentation

# Case Study (circa 1980): New Permanent Magnet to Replace $\text{SmCo}_5$

1. Sm and Co too expensive, supply of Co uncertain due to political instability in Zaire.
2. Compounds with same structure as  $\text{SmCo}_5$  don't form with Fe (which is much cheaper). In analogy with  $\text{SmCo}_5$  want uniaxial compound with large amount of Fe and a more abundant light rare earth.
3. In rare earth compounds with iron, spin of iron couples antiferromagnetically with spin on rare earth ion. For rare earths orbital moment is often much larger (than spin part) and for lighter rare earths is in direction opposite to spin moment. For light rare earths the net magnetic moment is in the same direction as the transition metal.
4. Based on these considerations one should look for a Nd-Fe magnet- but no suitable binary compounds. Thus want small amount of third element to stabilize new crystal structure. Boron works well-  $\text{Nd}_2\text{Fe}_{14}\text{B}$  discovered 1984 – 68 atoms in conventional tetragonal unit cell

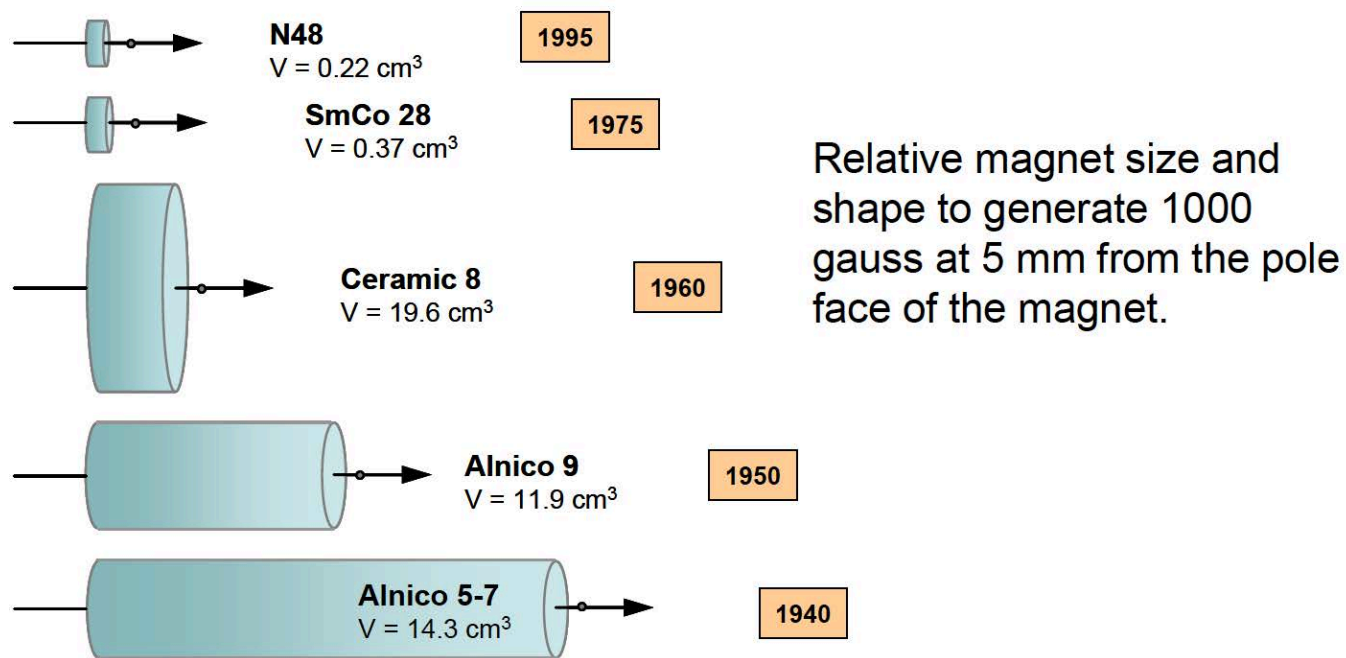

# Current Rare Earth Permanent Magnets based on $\text{Nd}_2\text{Fe}_{14}\text{B}$

- $\text{Nd}_2\text{Fe}_{14}\text{B}$  discovered/developed in 1984 to replace  $\text{SmCo}_5$ - partially as response to instability of cobalt supply from Zaire
- An expensive heavy rare earth, Dy, is added to improve magnet performance in electric motors and generators
- Both Nd and Dy in short supply

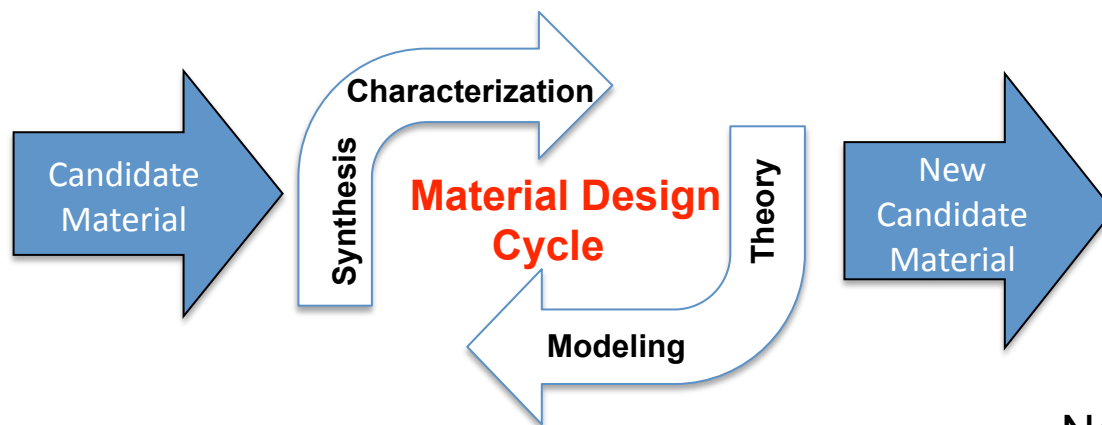

# Why is a new stronger permanent magnet such a big deal?

## Relative Magnet Sizes

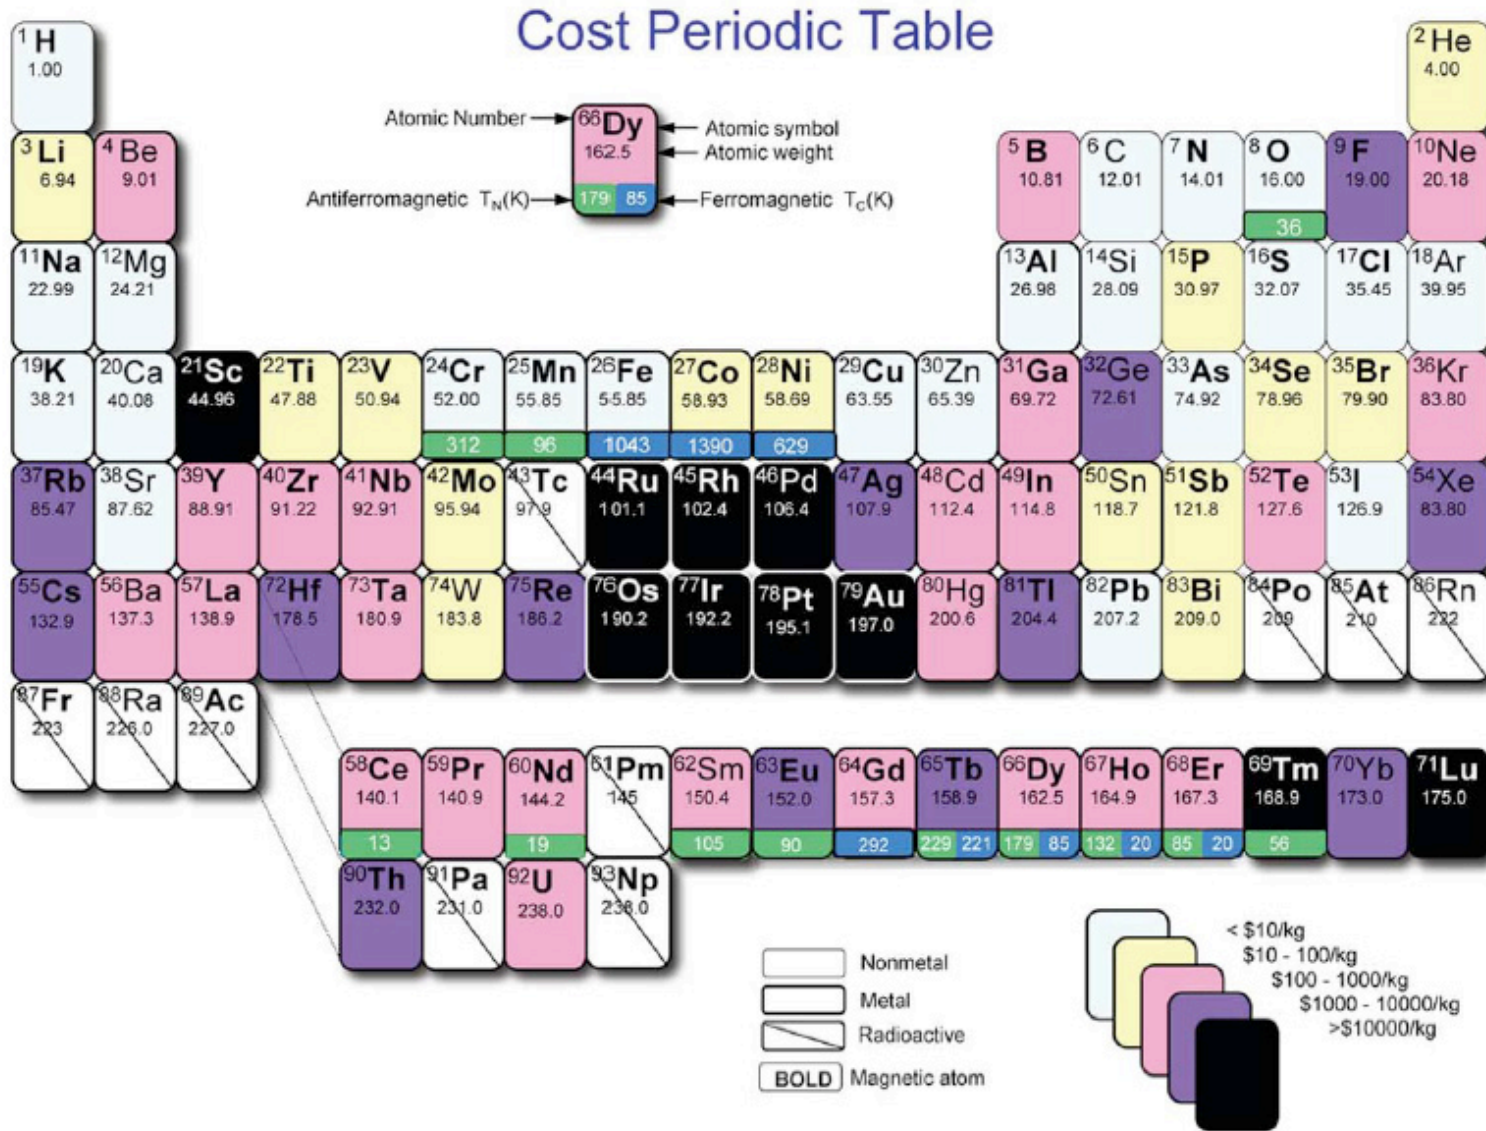

# Solution: Develop/Discover New Permanent Magnets That Use Less Rare Earths

- Integrated synthesis and theory at Ames and Oak Ridge.
- Explore selected ternary phase compositions for transition metal rich magnets
- Theory used to understand results and suggest improved compositions
- New magnets with reduced rare earth content licensed to US manufacturers

- Importance of “Mesoscale” ( metallurgy, microstructure, defects) in magnetic performance of  $\text{Nd}_2\text{Fe}_{14}\text{B}$
- Screening guide for identifying superconductors with an unusual pairing mechanism

# Importance of "mesoscale" in permanent magnets

Large single crystals are useless as permanent magnets (multiple domain formation demagnetizes most of sample)

Single Crystal Magnetization Data for  $\text{Nd}_2\text{Fe}_{14}\text{B}$

# Importance of “mesoscale” in permanent magnets

- Ideal microstructure for  $\text{Nd}_2\text{Fe}_{14}\text{B}$ : grains should be near 0.3 micron in size, with relatively smooth surface and grain boundary layer between grains. This microstructure is suppose to increase resistance to demagnetization and reduce nucleation of domain walls.
- In theory, a better control of the microstructure could increase the energy product (performance) by a factor of 2 or 3.

FIG. 6. SEM micrograph showing the fractured surface of (a) ToughNEO™ and (b) commercial NdFeB-type magnets.

Modeling could help understand the role of microstructure and defects

# Thermal Conductivity of Superconductors

## Hypothesis:

“Normal” SC’s- electron-phonon pairing- Kappa decreases below  $T_c$

“Exotic” SC’s with pairing partially due to magnetic fluctuations  
Kappa increases below  $T_c$

FIG. 1. Thermal conductivity of  $\text{Nb}_3\text{Sn}$  (sample FS14) as a function of temperature.

# Superconductivity, unusual magnetism and a good thermoelectric:

## $\text{Mo}_3\text{Sb}_7$ and related alloys

### Background for $\text{Mo}_3\text{Sb}_7$ :

1. Cubic at room temperature (Im3m space group)
2. Doped alloys show good thermoelectric performance at high temperatures (Ni, Mg, or Cu in cubic voids, or Ru for Mo or Te for Sb) – [Candalfi, 2007]- maximum  $ZT \approx 0.9$  at 1000 K
3. Magnetic susceptibility exhibits Curie-Weiss behavior above 200 K and broad maximum at 150 K. Cubic to tetragonal phase transition  $\approx 50$  K, also possible spin gap, formation of Mo-Mo dimers? [Tran 2008]
4. Is superconductivity at 2.3 K unconventional?

$\text{Mo}_3\text{Sb}_7$  crystal structure showing only Mo atoms and dimers

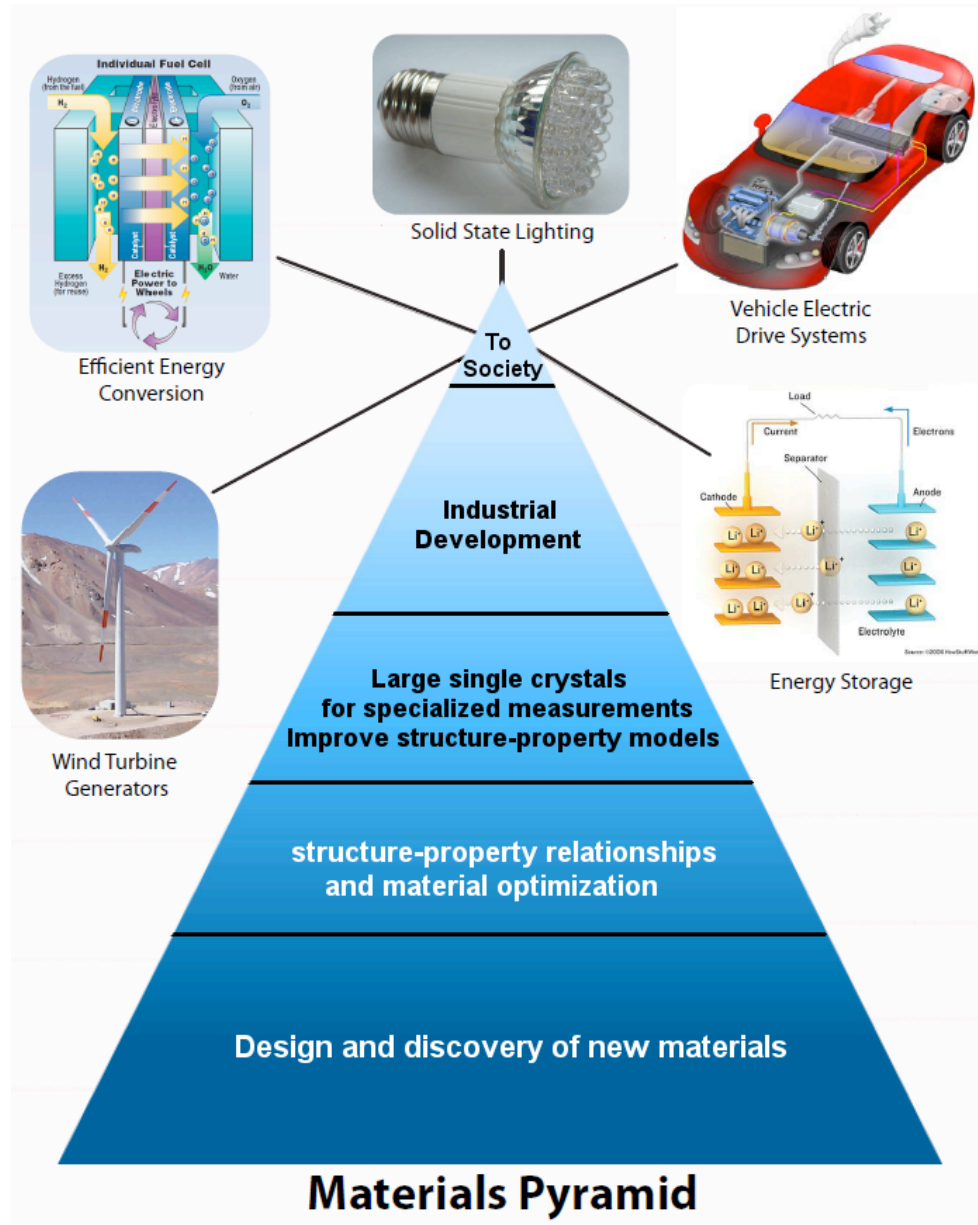

# Mo<sub>3</sub>Sb<sub>7</sub> : Thermal Conductivity Increases Below T<sub>c</sub> !

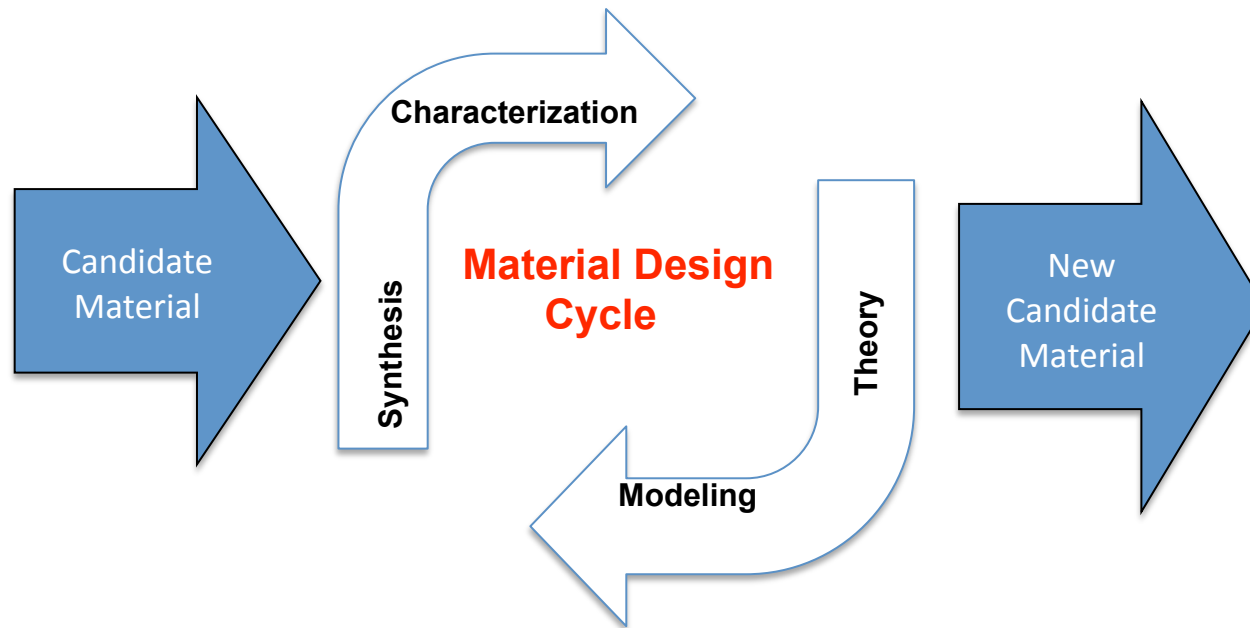

*Jiaqiang Yan*

# Where do new materials come from?

Need  
To do  
Better  
Than  
18 Years!

In my experience, in finding a new material theory is at best akin to a compass rather than a GPS system

Rapid feedback between experiment and theory is still the best approach to speed the design of a new material for the foreseeable future.

## Interesting Material Properties and Sample Availability Data Bases:

# and.. new technologies

# Magnons and Phonons can both Carry Heat

$$\kappa_i \approx C_i v_i d_i$$

# Heat Transport In Low Dimensional Magnetic Compounds

## Example: Spin Ladder Compound $\text{Ca}_9\text{La}_5\text{Cu}_{24}\text{O}_{41}$

**Key Observation: Huge magnon contribution to heat transport- even at room temperature!**

C. Hess et al., Phys. Rev B.  
64 (2001) 184305

# CrSb<sub>2</sub> Magnetic and Electrical Properties

Weak anomaly at  $T_N$  in magnetic susceptibility and resistivity data suggests low-dimensional magnetism

Magnetic Structure CrSb<sub>2</sub> – 2 $\mu_B$  per Cr

Resistivity data suggests two gaps: valence band-conduction band gap  $\approx 100$  meV and a donor level 14-16 meV below conduction band edge.

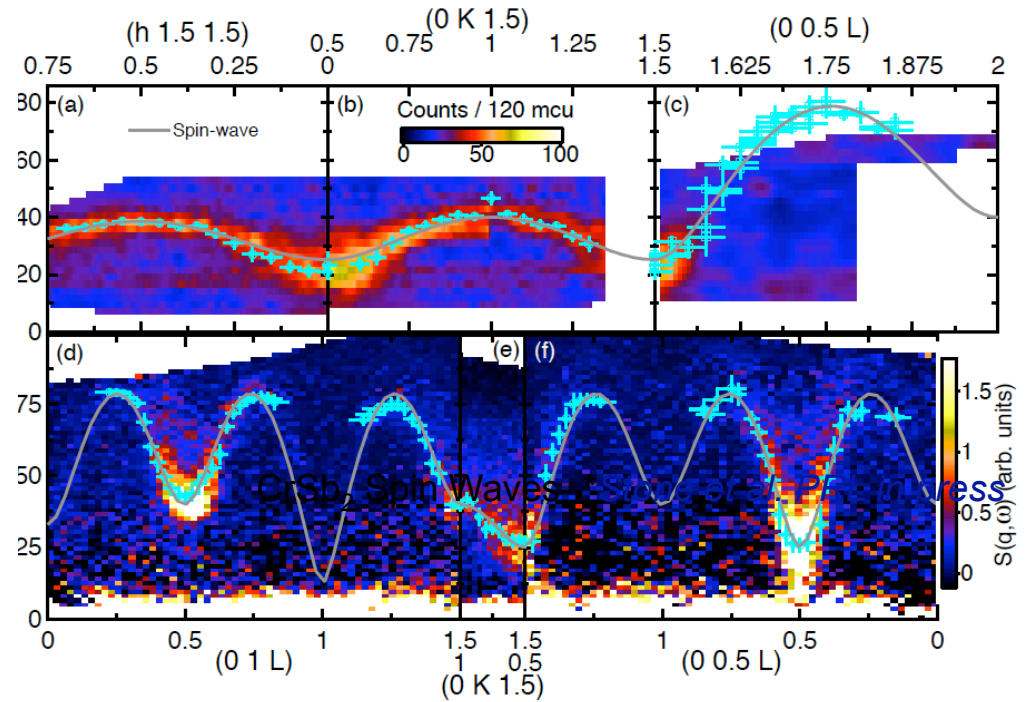

# CrSb<sub>2</sub>: Elastic and Inelastic Neutron Scattering

Quasi 1-d Antiferromagnetic Semiconductor: CrSb<sub>2</sub>  
Orders Magnetically at 273 K

$$J_c = 35 \text{ meV}$$

$$J_a \approx J_b \approx J_{111} \approx 1 \text{ meV}$$

Stone et al. PRL 108 (2012) 054515

## Thermal Conductivity Data from CrSb<sub>2</sub>

Below 50 K ,  $\kappa$  similar in both directions- consistent with **gap for magnetic excitations** measured using neutron scattering ( $\approx 25$  meV)

Deviation above 50 K consistent with either magnon heat conduction along c or increased scattering of phonons by magnons

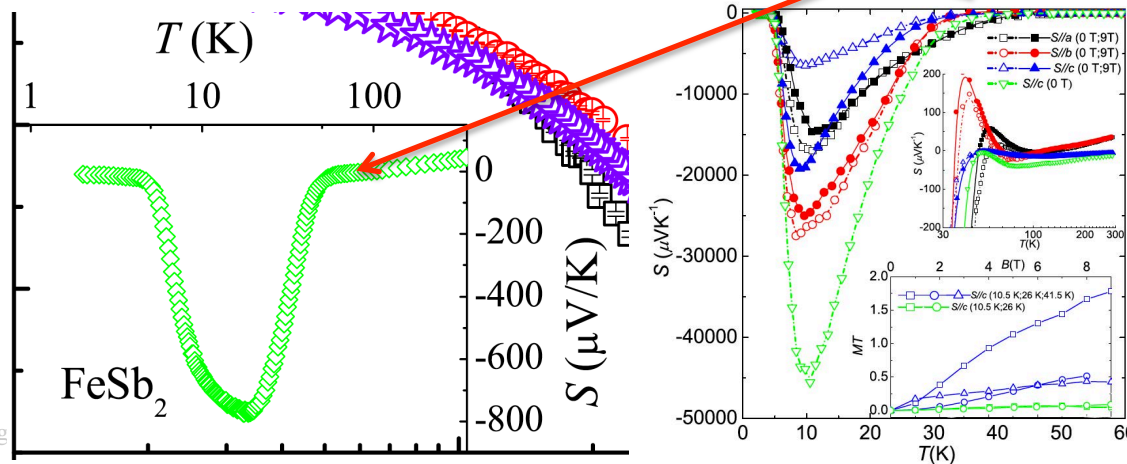

*Stone et al. PRL 108 (2012) 054515*

# Seebeck Data from CrSb<sub>2</sub>

*Sales et al -  
in press*

Large Seebeck Coefficient  $\approx -4500 \mu\text{V/K}$  at 18 K  
unusual asymmetric shape – very similar to FeSb<sub>2</sub>

Bentien et al.  
EPL 80 (2007)  
17008

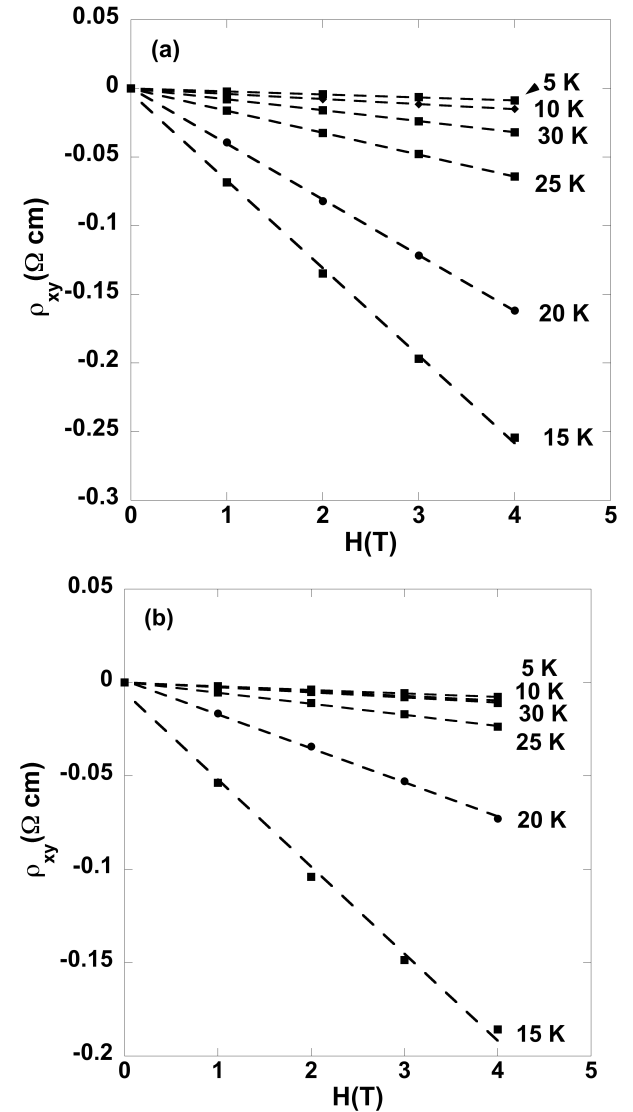

Wang et al. JAP 112  
(2012) 013703

## Hall Data from CrSb<sub>2</sub>

Note sharp minimum in apparent carrier concentration.  
 Similarity of Hall and Seebeck data below 30 K.  
 A sharp minimum also can occur in doped Ge crystals

## Simple Explanation of Hall Data from CrSb<sub>2</sub>

$$N_{\text{con}} = 3 \times 10^{17} \frac{G \exp(-\Delta/k_B T)}{1 + G \exp(-\Delta/k_B T)}$$

$$n_{\text{app}} = \frac{(N_{\text{imp}} + N_{\text{con}} b)^2}{N_{\text{imp}} + N_{\text{con}} b^2}$$

$$b \approx 130$$

$$G \approx 100$$

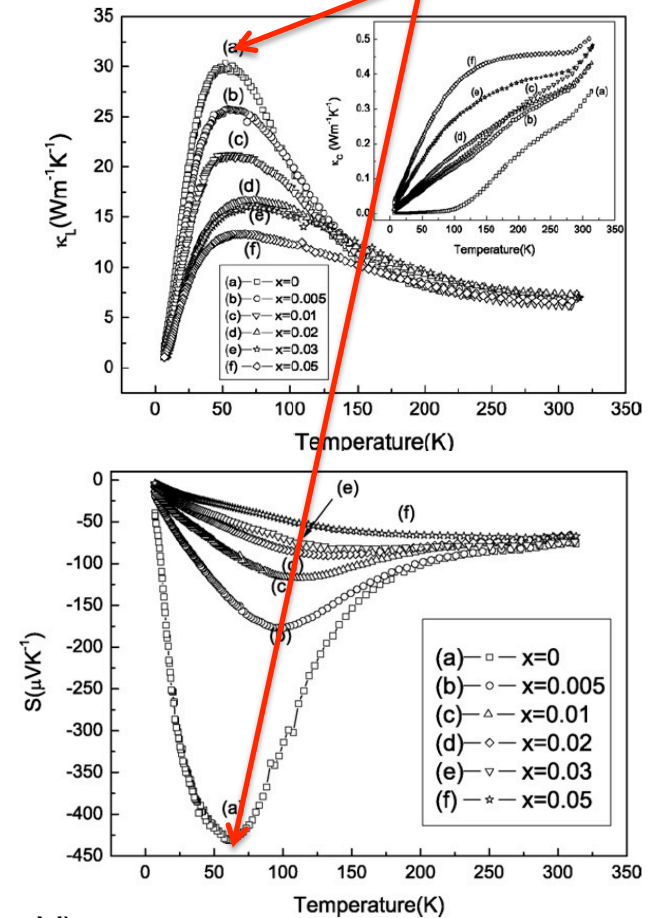

Note sharp minimum in apparent carrier concentration.

Similarity of Hall and Seebeck data below 30 K.

A sharp minimum also can occur in doped Ge crystals, and FeSb<sub>2</sub>

# Thermal Conductivity Data from CrSb<sub>2</sub> Polycrystalline CrSb<sub>2</sub>

Below 50 K,  $\kappa$  similar in both directions- consistent with **gap for magnetic excitations** measured using neutron scattering ( $\approx 25$  meV)

Deviation above 50 K consistent with either magnon heat conduction along c or increased scattering of phonons by magnons

Note: Large value of  $\kappa$  at 18 K consistent with phonon-drag mechanism as likely origin of large peak in Seebeck data **For polycrystalline CrSb<sub>2</sub>- both  $\kappa$  and S are 10 times smaller**

## No Evidence of Significant Mass Enhancement for Carriers in CrSb<sub>2</sub>

# Relevance of Research to DOE Energy Mission:

Superconducting generators for large (> 10 MW wind turbines)

Magnets for electric motors

Thermoelectric materials for waste heat recovery- for cars to improve gas mileage

Note: All these energy applications require “bulk” quantities of material

## Unusual Crystal Structure of Cubic FeSi

FeSi

- *No inversion symmetry*
- *Fe is coordinated by 7 Si:  
2.294 Å, 2.341 Å (x3), 2.515 Å (x3)*
- *Si coordinated by 7 Fe*
- *Fe-Fe nnn 2.753 Å*
- *Fe-Fe nn distance in bcc Fe metal: 2.482 Å*

**FeSi is a narrow gap semiconductor ( $E_g \approx 0.1$  eV)**  
**Possible material for low temperature (80 K) solid-state refrigeration?**

**Sharp peaks in the electronic density of states at both the conduction band and valence band edges**

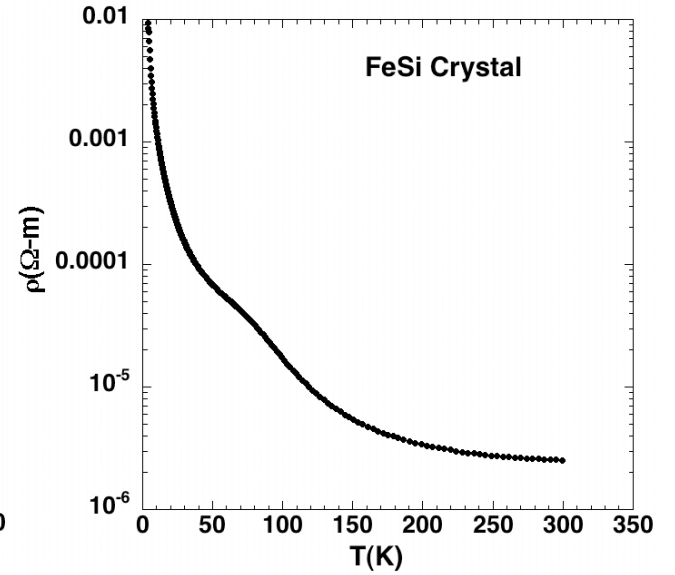

Delaire et al. PNAS (2011)

Klein et al. PRL 101 (2008) 046406

**Note: for this material and related monosilicides DFT seems to get the gap and the sharp peaks in the DOS pretty close to experiment**

## Transport Properties of FeSi (single crystal)

Debye Temperature  $\approx 460$  K  
Sound velocity  $\approx 3500$  m/sec

## Transport properties of FeSi Polycrystalline sample with *lower* extrinsic carrier concentration

At 50K 99% of heat carried by phonons (WF)  
yet change in carrier concentration produces  
factor of 2 change in Kappa -**electron-phonon scattering**

**Thermoelectric properties not very good ( $ZT \approx 0.013$  at 70 K)**  
**Need to Dope it !**

# How to “dope” a semiconductor ?

## Very difficult to theoretically predict

He formulated his discovery in a periodic table of elements, now regarded as the backbone of modern chemistry.  The crowning achievement of Mendeleev's periodic table lay in his prophecy of then undiscovered elements. In 1869, the year he published his periodic classification, the elements gallium, germanium and scandium were unknown. Mendeleev left spaces for them in his table and even predicted their atomic masses and other chemical properties. Six years later, gallium was discovered and his predictions were found to be accurate. Other discoveries followed and their chemical behaviour matched that predicted by Mendeleev.  This remarkable man, the youngest in a family of 17 children, has left the scientific community with a classification system so powerful that it became the cornerstone in chemistry teaching and the prediction of new elements ever since. In 1955, element 101 was named after him: Md, Mendelvium.										<b>Al</b> Aluminium 13 26.98	<b>Si</b> Silicon 14 28.09	<b>P</b> Phosphorus 15 30.97	<b>S</b> Sulphur 16 32.06	<b>Cl</b> Chlorine 17 35.45	<b>Ar</b> Argon 18 39.95

## Co vs Ir doping

Greater decrease in kappa with Ir doping explainable by point defect scattering formula derived by Klemens (1955)

Goes like  $(1 - M_{\text{dopant}}/M_{\text{av}})^2$

Thermoelectric values of all three properties better with Ir doping, but  $ZT_{\text{MAX}} = 0.08$  at 90 K

## Os (isoelectronic with Fe) vs Ir doping

Os doping- not much change in carrier concentration (relative to FeSi single crystal)

Ir and Os have similar masses :similar point defect scattering

Note common approximation of independent  $\kappa_{Lattice}$  :  
 $\kappa = \kappa_{electronic} + \kappa_{Lattice}$  not  
 valid with strong electron-phonon scattering

## Co vs Ir doping

Greater decrease in kappa with Ir doping explainable by point defect scattering formula derived by Klemens (1955)

Goes like  $(1 - M_{\text{dopant}}/M_{\text{av}})^2$

Thermoelectric values of all three properties better with Ir doping, but  $ZT_{\text{MAX}} = 0.08$  at 90 K

What about nanostructuring FeSi alloys?

**Nanostructuring to lower Lattice Thermal Conductivity  
without comparable lowering of electrical conductivity:  
Net increase in ZT**

**Key Idea :**  
**mean free path electrons  $\ll$  grain size  $\ll$  mean free path phonons**

Examples of bulk systems where nanostructuring has improved ZT (Minnich et al. Energy&Env. Sci 2 (2009) 466)

# Does “Nanostructuring” $\text{Fe}_{0.96}\text{Ir}_{0.04}\text{Si}$ Increase ZT?

## Samples of $\text{Fe}_{0.96}\text{Ir}_{0.04}\text{Si}$ Prepared 3 different ways:

1. Arc-melt elements together, slow cooling  
**grains** **mm size**
2. Arc-melt elements/ coarse ball mill 1h/Spark Plasma Sintering (SPS) near theoretical density  
**micron size grains,** **mainly 20-100**  
**some smaller**
3. Arc-melt elements/coarse ball mill 1h/  
h SPS to theoretical density **planetary mill 40**  
**micron** **mainly less than 100**  
**some smaller**

Broadening of X-ray peaks from plan milled powder suggest grains  $\approx 20$  nm

Energy

# ORNL Spark-Plasma Sintering System:

≈ 1000 Amps  
≈ 800 kg (3/4" sample)

# “Nanostructuring” $\text{Fe}_{0.96}\text{Ir}_{0.04}\text{Si}$ - Transport Properties

Resistivity and Seebeck Not Effected by Grain Size

BUT

# “Nanostructuring” - 50% increase in ZT max due to decrease in thermal conductivity

# Should Nanostructuring $\text{Fe}_{0.96}\text{Ir}_{0.04}\text{Si}$ Work ?

Electron mean free path:

$$d_{\text{electron}} = 1.5\pi\hbar / (e^2 k_F^2 \rho) \approx 3\text{nm}$$

At 90 K (8meV) mainly  
acoustic phonons excited  
from

$$\kappa = 1/3 C_v v_s d$$

$$d_{\text{phonon}} \approx 4\text{nm}$$

Not very Encouraging!  
(analysis too simple!)

Phonon wavelength not considered  
Which phonons are carrying heat?

## Summary and Conclusions

1. Correlations don't seem to be that important in FeSi- DFT does a pretty good job. Many of other “anomalies” concerning material related to thermal disorder, small gap and effects of coupling between electrons and phonons – [Discussed in next talk](#)
2. Doping a semiconductor- need theory of which dopants will work the best
3. Illustrated why common approximation of independent  $\kappa_{\text{Lattice}}$  :  
 $\kappa = \kappa_{\text{electronic}} + \kappa_{\text{Lattice}}$  clearly not valid with strong electron-phonon scattering
4. ZT of  $\text{Fe}_{0.96}\text{Ir}_{0.04}\text{Si}$  enhanced by 50% by starting with small grains- need to increase further by a factor of 6 to be useful
5. To effectively use nanostructuring, there has to be a better fundamental understanding of which phonons (wavelength and energy) carry heat and how much.- theory

## Effects of electronic structure on phonons (Main thrust of Olivier Delaire's research at ORNL)

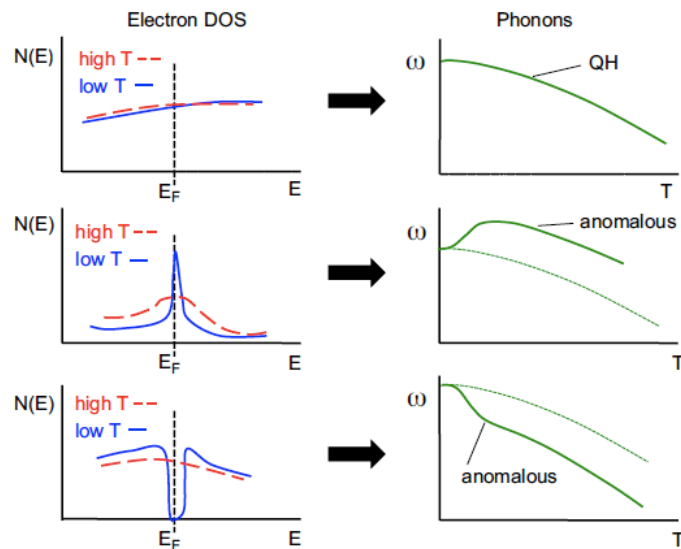

FIG. 1: Trends in the temperature dependence of phonon energies for different electronic densities of states (DOS). The Fermi energy is denoted by  $E_F$ , and  $\langle\omega\rangle$  represents an average phonon energy, as function of temperature  $T$ .

First principles electronic structure  
Calculations for FeSi and CoSi

# Phonon DOS from Inelastic Neutron Scattering Delaire et al. submitted PRL

Conclusions: **Thermal disorder** plus strong coupling between electrons and phonons in FeSi leads to anomalous softening of phonons with temperature. At the same time the renormalization of the electronic structure induces a semiconductor-to-metal transition with increasing temperature. **Net Result: T=0 gap of FeSi (0.15 eV) closes at a relatively low temperature  $\approx$  200-300 K.**

# Ball Mill vs Planetary Mill: $\text{Fe}_{0.96}\text{Ir}_{0.04}\text{Si}$

Ball Mill 2h/ Ar gas

Plan Mill 40 h/ He gas
